# Public Key CryptoSystems - PKCS

## 1. Principles of Public Key Cryptography

Instead of using single symmetric key shared in advance by the parties for realization of symmetric cryptography, asymmetric cryptography uses two *mathematically* related keys named as private key and public key we denote by **PrK** and **PuK** respectively.

**PrK** is a secret key owned personally by every user of cryptosystem and must be kept secretly. Due to the great importance of **PrK** secrecy for information security we labeled it in red color. **PuK** is a non-secret personal key and it is known for every user of cryptosystem and therefore we labeled it by green color. The loss of **PrK** causes a dramatic consequences comparable with those as losing password or pin code. This means that cryptographic identity of the user is lost. Then, for example, if user has no copy of **PrK** he get no access to his bank account. Moreover his cryptocurrencies are lost forever. If **PrK** is got into the wrong hands, e.g. into adversary hands, then it reveals a way to impersonate the user. Since user's **PuK** is known for everybody then adversary knows his key pair (**PrK**, **Puk**) and can forge his Digital Signature, decrypt messages, get access to the data available to the user (bank account or cryptocurrency account) and etc.

Let function relating key pair ( $\mathbf{PrK}$ ,  $\mathbf{Puk}$ ) be F. Then in most cases of our study (if not declared opposite) this relation is expressed in the following way:

**PuK=F(PrK)**.

In open cryptography according to Kerchoff principle function F must be known to all users of cryptosystem while security is achieved by secrecy of cryptographic keys. To be more precise to compute **PuK** in function F must be defined using some parameters named as public parameters we denote by **PP** and color in blue that should be defined at the first step of cryptosystem creation. Since we will start from the cryptosystems based on discrete exponent function then these public parameters are

 $\mathbf{PP} = (\boldsymbol{p}, \boldsymbol{g}).$ 

Notice that relation represents very important cause and consequence relation we name as the direct

relation: when given **PrK** we compute **PuK**.

Let us imagine that for given F we can find the inverse relation to compute **PrK** when **PuK** is given. Abstractly this relation can be represented by the inverse function  $F^{-1}$ . Then

#### **PrK**=*F*<sup>-1</sup>(**PuK**).

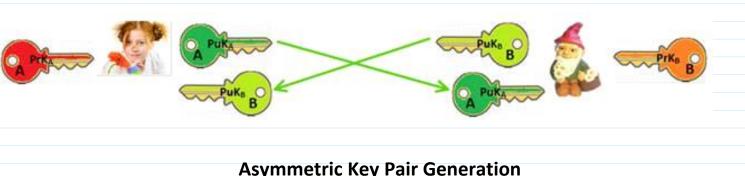

In this case the secrecy of **PrK** is lost with all negative consequences above. To avoid these undesirable consequences function F must be **one-way function** – OWF. In this case informally OWF is defined in the following way:

1. The computation of its direct value **PuK** when **PrK** and **F** in are given is effective.

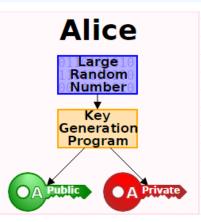

2. The computation of its inverse value **PrK** when **PuK** and **F** are given is infeasible, meaning that to find  $F^{-1}$  is infeasible.

The one-wayness of F allow us to relate person with his/her **PrK** through the **PuK**. If F is 1-to-1, then the pair (**PrK**, **Puk**) is unique. So **PrK** could be reckoned as a unique secret parameter associated with certain person. This person can declare the possession or **PrK** by sharing his/her **PuK** as his public parameter related with **PrK** by and and at the same time not revealing **PrK**. So, every user in asymmetric cryptography possesses key pair (**PrK, PuK**). Therefore, cryptosystems based on asymmetric cryptography are named as **Public Key CryptoSystems** (PKCS).

We will consider the same two traditional (canonical) actors in our study, namely Alice and Bob. Everybody is having the corresponding key pair ( $\mathbf{PrK}_A$ ,  $\mathbf{PuK}_A$ ) and ( $\mathbf{PrK}_B$ ,  $\mathbf{PuK}_B$ ) and are exchanging with their public keys using open communication channel as indicated in figure below.

## Asymmetric Key Pair Generation

PrK and PuK are mathematically rela	ted by One-Way Function:
,	
PuK = F(PrK)	

**F** is one-way function - OWF if:

- 1. For given **F** defined by public parameters and **PrK**
- it is easy to compute PuK.
- 2.For given **F** and **PuK** it is infeasible to find **PrK** = **F**<sup>-1</sup>(**PuK**).

**Public Parameters PP = (p, g)**: for **F** definition **PrK** = *x* <-- randi ==> **PuK** = *a* = g<sup>x</sup> mod p

### 2.Private Keys Prk and public Public Keys PuK generation.

# $PrK_{A} = x = randi(p-1)$ a = g<sup>x</sup> mod p PuK\_{A} = a = mod\_exp(g,x,p)

 $PrK_{B} = y = randi(p-1)$ b = g<sup>y</sup> mod p  $PuK_{B} = b = mod_exp(g,y,p)$ 

#### **1. Identification.**

If person can prove that he/she knows **PrK** corresponding to his/her **PuK** without revealing any information about **PrK** then everybody can trust that he is communicating with person posessing (**PrK**, **Puk**) key pair. This kind of proof is named as **Zero Knowledge Proof** (ZKP) and plays a very important role in cryptography. It is very useful to realize identification, Digital Signatures and many other cryptographically secure protocols in internet. In many cryptographic protocols, especially in identification protocols **PrK** is named as **witness** and **PuK** as a **statement** for **PrK**. Every actor is having the corresponding key pair (**PrK**<sub>A</sub>, **PuK**<sub>A</sub>) and (**PrK**<sub>B</sub>, **PuK**<sub>B</sub>) and are exchanging with their public keys using open communication channel as indicated in figure below. Let Bob is sure that **PuK**<sub>A</sub> is of Alice and wants to tell Alice that he intends to send her his photo with chamomile flowers dedicated for Alice. But he wants to be sure that he is communicating only with Alice itself and with nobody else. He hopes that at first Alice will prove him that she knows her secret **PrK**<sub>A</sub> using ZKP protocol. In general, this protocol is named as identification protocol, is interactive and has 3 communications to exchange the following data named as *commitment*, *challenge* and *response*.

**Registration phase**: Bank generates  $PrK_A = x$  and  $PuK_A = a$  to Alice and hands over this data in smart card, or other crypto chip in Alice's smart phone, or in software for Smart ID.

Schnorr Id Scenario: Alice wants to prove **Bank** that she knows her <mark>Private Key</mark> - **PrK<sub>A</sub>** which corresponds to her <mark>Public Key</mark> - **PuK<sub>A</sub>** not revealing **PrK<sub>A</sub>**: Zero Knowledge Proof - ZKP Protocol execution between Alice and Bank has time limit.

Alice's computation resources has a limit --> protocol must be computationally effective.  $PrK_A=x$  is called a witness and corresponding  $PuK_A=a=g^x \mod p$  is called a statement. This protocol is initiated by Alice and has the following three communications.

P(x, a) - Prover - Alice

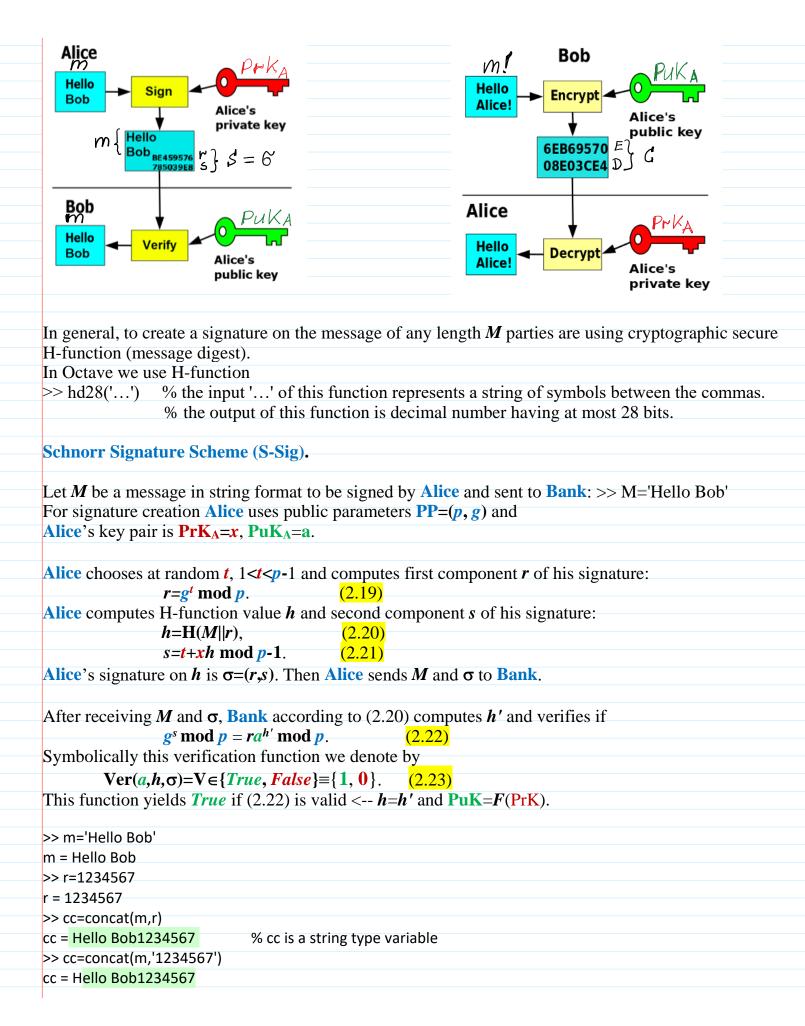

V(a) - Verifier - Bank

## Public Parameters PP = (p, g)

- 1. Alice generates at random secret random number u = randi(p-2) and using PP = (p, g)
- 2. computes **commitment** *t* in the following way

 $t - \sigma^{\mu} \mod n \quad t \in \mathbf{7} \quad = \int (1 \quad 2 \quad n_{-} 2)$ 

	Alice generates at random secret random number $u$ =randi( $p$ -2) and using PP=( $p$ , $g$ ) computes commitment $t$ in the following way	
	$t=g^{u} \mod p, t \in \mathbb{Z}_{p-1}=\{0, 1, 2,, p-2\}$	
	Alice sends $t$ and $a$ to Bank.	÷
3.	<b>Bank</b> generates at random <b>challenge</b> <i>h</i> = <b>randi</b> ( <i>p</i> -2) and sends <i>h</i> to Alice.	1.
1	All an after respiring L computes has non-ange neg boying has private her a together	h -
	Alice after receiving $h$ computes her <b>response</b> res having her private key $x$ together with previously generated secret number $u$ :	
5.	<i>res</i> = $u+xh \mod p-1$ ; <i>res</i> $\in \mathbb{Z}_{p-1}=\{0, 1, 2, 3,, p-2\}$	
	Alice sends $r$ to the Bank.	res -
		$\checkmark$
	After the third communication <b>Bank</b> verifies if the following identity holds:	Time
	$g^{res}=ta^h \mod p.$	
	P(x, a) - Prover - Alice V(a) - Verifier - Bank	
	$X \leftarrow randi(Z_{p-1}); \alpha = q^{\times} \mod p$	
	$\chi = found (dp-1), u = g mou p$	
	$1 \circ ( \sim ) \qquad \qquad$
